Factor Analysis

Let the observable vector $\mathbf{y} \in \mathbb{R}^p$ be written as

$$\mathbf{y} = \mathbf{W}\mathbf{x} + \boldsymbol{\mu} + \boldsymbol{\epsilon},$$

where

- ① $\mathbf{W} \in \mathbb{R}^{p \times q}$ is the loading matrix (parameter),
- ② $\mathbf{x} \in \mathbb{R}^q$ is the common factor (parameter/random vector),
- ③ $\boldsymbol{\mu} \in \mathbb{R}^p$ is the mean vector (parameter),
- ④ $\boldsymbol{\epsilon} \in \mathbb{R}^p$ is the specific factor (random vector).

The model is similar to regression, but \mathbf{x} is unobserved.

Factor Analysis

Example of sports games:

$$y = Wx + \mu + \epsilon.$$

- ① **y**: performance in real-world
- ② **W**: system of the game
- ③ **x**: attributes in the game
- ④ μ : average attributes
- ⑤ ϵ : noise/exception

- 4 Course Summary

Probabilistic Principle Component Analysis

Let $\mathbf{y}_1, \dots, \mathbf{y}_N \in \mathbb{R}^p$ be N independent observations and we have

$$\mathbf{y}_\alpha = \mathbf{W}\mathbf{x}_\alpha + \boldsymbol{\mu} + \epsilon_\alpha,$$

where

$$\mathbf{x}_\alpha \sim \mathcal{N}_q(\mathbf{0}, \mathbf{I}) \quad \text{and} \quad \epsilon_\alpha \sim \mathcal{N}_p(\mathbf{0}, \sigma^2 \mathbf{I})$$

are independent for some $\sigma^2 > 0$ and $q < p$.

We target to estimate parameters

$$\mathbf{W} \in \mathbb{R}^{p \times q}, \quad \boldsymbol{\mu} \in \mathbb{R}^p \quad \text{and} \quad \sigma \in (0, +\infty)$$

by maximum likelihood estimation for given $\mathbf{y}_1, \dots, \mathbf{y}_N$.

Probabilistic Principle Component Analysis

Consider that

$$\mathbf{y}_\alpha \sim \mathcal{N}_p(\boldsymbol{\mu}, \mathbf{W}\mathbf{W}^\top + \sigma^2\mathbf{I}).$$

We construct the likelihood function

$$\begin{aligned} & L(\boldsymbol{\mu}, \mathbf{W}, \sigma^2) \\ &= \prod_{\alpha=1}^N \frac{1}{\sqrt{(2\pi)^p \det(\boldsymbol{\Sigma})}} \exp\left(-\frac{1}{2}(\mathbf{y}_\alpha - \boldsymbol{\mu})^\top (\mathbf{W}\mathbf{W}^\top + \sigma^2\mathbf{I})^{-1}(\mathbf{y}_\alpha - \boldsymbol{\mu})\right), \end{aligned}$$

then we have

$$\begin{aligned} & \ln L(\boldsymbol{\mu}, \mathbf{W}, \sigma^2) \\ & \propto -\frac{N}{2} \ln \det(\mathbf{W}\mathbf{W}^\top + \sigma^2\mathbf{I}) - \frac{1}{2} \sum_{\alpha=1}^N (\mathbf{y}_\alpha - \boldsymbol{\mu})^\top (\mathbf{W}\mathbf{W}^\top + \sigma^2\mathbf{I})^{-1}(\mathbf{y}_\alpha - \boldsymbol{\mu}). \end{aligned}$$

The Maximum Likelihood Estimators

The maximum likelihood estimators of μ , \mathbf{W} and σ^2 are

$$\hat{\mu} = \bar{\mathbf{y}} = \frac{1}{N} \sum_{\alpha=1}^N \mathbf{y}_{\alpha}, \quad \hat{\mathbf{W}} = \mathbf{U}_q (\mathbf{\Lambda}_q - \hat{\sigma}^2 \mathbf{I}) \mathbf{R} \quad \text{and} \quad \hat{\sigma}^2 = \frac{1}{d-q} \sum_{j=q+1}^d \lambda_j,$$

where

- 1 $\mathbf{U}_q \in \mathbb{R}^{p \times q}$ is orthogonal column consisting of principal eigenvectors of

$$\hat{\mathbf{\Sigma}} = \frac{1}{N} \sum_{\alpha=1}^N (\mathbf{y}_{\alpha} - \bar{\mathbf{y}})(\mathbf{y}_{\alpha} - \bar{\mathbf{y}})^{\top},$$

- 2 $\mathbf{\Lambda}_q \in \mathbb{R}^{q \times q}$ is diagonal with corresponding eigenvalues $\lambda_1, \dots, \lambda_q$,
- 3 $\mathbf{R} \in \mathbb{R}^{q \times q}$ is any orthogonal matrix.

The Maximum Likelihood Estimators

The maximum likelihood estimators also minimize the error with respect to Frobenius norm

$$(\hat{\mathbf{W}}, \hat{\sigma}^2) = \arg \min_{\mathbf{W} \in \mathbb{R}^{p \times q}, \sigma^2 \in \mathbb{R}^+} \left\| \hat{\mathbf{\Sigma}} - (\mathbf{W}\mathbf{W}^\top + \sigma^2 \mathbf{I}) \right\|_F.$$

Outline

- 1 Factor Analysis
- 2 Probabilistic Principle Component Analysis
- 3 The Expectation-Maximization Algorithm**
- 4 Course Summary

The Expectation-Maximization Algorithm

For the model

$$\mathbf{y} = \mathbf{W}\mathbf{x} + \boldsymbol{\mu} + \epsilon,$$

where $\mathbf{x} \sim \mathcal{N}_q(\mathbf{0}, \mathbf{I})$ and $\epsilon \sim \mathcal{N}_p(\mathbf{0}, \sigma^2 \mathbf{I})$ are independent.

We regard $\{\mathbf{x}_\alpha\}_{\alpha=1}^N$ as missing data and $\{\mathbf{x}_\alpha, \mathbf{y}_\alpha\}_{\alpha=1}^N$ as the complete data, then we can achieve

$$\mathbf{y} | \mathbf{x} \sim \mathcal{N}_p(\mathbf{W}\mathbf{x} + \boldsymbol{\mu}, \sigma^2 \mathbf{I})$$

and

$$\mathbf{x} | \mathbf{y} \sim \mathcal{N}_q(\mathbf{M}^{-1} \mathbf{W}^\top (\mathbf{y} - \boldsymbol{\mu}), \sigma^2 \mathbf{M}^{-1}),$$

where $\mathbf{M} = \mathbf{W}^\top \mathbf{W} + \sigma^2 \mathbf{I}$.

The Expectation-Maximization Algorithm

The update of the EM algorithm

- 1 In E-step, we take the expectation

$$l_C = \mathbb{E} \left[\ln \left(\prod_{\alpha=1}^N f(\mathbf{x}_\alpha | \mathbf{y}_\alpha) \right) \right].$$

- 2 In the M-step, we maximized l_C with respect to \mathbf{W} and σ^2 :

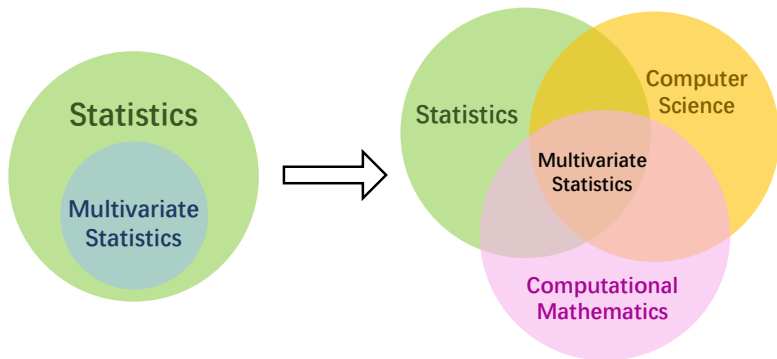

$$\begin{aligned} \mathbf{W}_+ &= \hat{\Sigma} \mathbf{W} (\sigma^2 \mathbf{I} + \mathbf{M}^{-1} \mathbf{W}^\top \hat{\Sigma} \mathbf{W})^{-1}, \\ \sigma_+^2 &= \frac{1}{p} \text{tr} \left(\hat{\Sigma} - \hat{\Sigma} \mathbf{W} \mathbf{M}^{-1} \mathbf{W}_+^\top \right). \end{aligned}$$

Note that the computational complexity of EM is $\mathcal{O}(Npq)$, while the spectral decomposition in MLE requires $\mathcal{O}(Np^2 + p^3)$.
