- 1 Noncentral Chi-Squared Distribution
- 2 Hypothesis Testing for the Mean (Covariance is Known)
- 3 Sample Correlation Coefficient

Hypothesis Testing for the Mean

In the univariate case, the difference between the sample mean and the population mean is normally distributed.

We consider

$$z = \frac{\sqrt{N}}{\sigma}(\bar{x} - \mu_0).$$

- 1 For significance level $\alpha = 0.05$ and $p = 1$, we have $1 - \alpha = 0.95$.
- 2 What about multivariate case?

Chi-Squared Distribution

If x_1, \dots, x_n are independent, standard normal random variables, then the sum of their squares,

$$y = \sum_{i=1}^n x_i^2,$$

is distributed according to the (central) chi-squared distribution (χ^2 -distribution) with n degrees of freedom. One may write $y \sim \chi_n^2$.

We have $\mathbb{E}[y] = n$ and $\text{Var}[y] = 2n$.

Chi-Squared Distribution

The probability density function of the (central) chi-squared distribution is

$$f(y; n) = \begin{cases} \frac{1}{2^{\frac{n}{2}} \Gamma(\frac{n}{2})} y^{\frac{n}{2}-1} \exp\left(-\frac{y}{2}\right), & y > 0; \\ 0, & \text{otherwise,} \end{cases}$$

where

$$\Gamma(\alpha) = \int_0^{+\infty} t^{\alpha-1} \exp(-t) dt.$$

Chi-Squared Distribution

The derivation for the density of Chi-square distribution:

- ① Show that $\Gamma(1/2) = \sqrt{\pi}$.
- ② For $y_1 = x^2$ with $x \sim \mathcal{N}(0, 1)$, the density function of y_1 is

$$\frac{1}{\sqrt{2\pi y_1}} \exp\left(-\frac{1}{2}y_1\right).$$

- ③ For beta function $B(\alpha, \beta) = \int_0^1 t^{\alpha-1}(1-t)^{\beta-1} dt$, we have

$$B(\alpha, \beta) = \frac{\Gamma(\alpha)\Gamma(\beta)}{\Gamma(\alpha + \beta)}.$$

- ④ Show the density of $y_n = \sum_{i=1}^n x_i^2$ by induction.

Noncentral Chi-Squared Distribution

If x_1, \dots, x_n are independent and each x_i are normally distributed random variables with means μ_i and unit variances, then the sum of their squares,

$$y = \sum_{i=1}^n x_i^2,$$

is distributed according to the noncentral Chi-squared distribution with n degrees of freedom and noncentrality parameter

$$\lambda = \sum_{i=1}^n \mu_i^2.$$

One may write $y \sim \chi_{n,\lambda}^2$.

We have $\mathbb{E}[y] = n + \lambda$ and $\text{Var}[y] = 2n + 4\lambda$.

Noncentral Chi-Squared Distribution

Theorem

If y_1, \dots, y_k are independent and each y_i is distributed according to the noncentral χ^2 -distribution with n_i degrees of freedom and noncentrality parameter λ_i , then

$$\sum_{i=1}^k y_i \sim \chi_{n,\lambda}^2,$$

where

$$n = \sum_{i=1}^k n_i \quad \text{and} \quad \lambda = \sum_{i=1}^k \lambda_i.$$

Noncentral Chi-Squared Distribution

Theorem

If the n -component random vector \mathbf{y} is distributed according to $\mathcal{N}_n(\boldsymbol{\nu}, \mathbf{T})$ with $\mathbf{T} \succ \mathbf{0}$, then

$$\mathbf{y}^\top \mathbf{T}^{-1} \mathbf{y} \sim \chi_{n,\lambda}^2,$$

where

$$\lambda = \boldsymbol{\nu}^\top \mathbf{T}^{-1} \boldsymbol{\nu}.$$

If $\boldsymbol{\nu} = \mathbf{0}$, the distribution is the central χ^2 -distribution.

Noncentral Chi-Squared Distribution

Let $\mathbf{y} \sim \mathcal{N}_p(\boldsymbol{\lambda}, \mathbf{I})$, then

$$v = \mathbf{y}^\top \mathbf{y}$$

is distributed according to the noncentral χ^2 -distribution with p degrees of freedom and noncentral parameter $\lambda = \boldsymbol{\lambda}^\top \boldsymbol{\lambda}$.

The probability density function is

$$f(v; p, \lambda) = \begin{cases} \sum_{\beta=0}^{\infty} \frac{(\lambda/2)^\beta \exp(-(\lambda/2))}{\beta!} \cdot \frac{1}{2^{\frac{p+2\beta}{2}} \Gamma(\frac{p}{2} + \beta)} v^{\frac{p}{2} + \beta - 1} \exp\left(-\frac{v}{2}\right) & v > 0, \\ 0, & v \leq 0. \end{cases}$$

Noncentral Chi-Squared Distribution

- 1 Noncentral Chi-Squared Distribution
- 2 Hypothesis Testing for the Mean (Covariance is Known)
- 3 Sample Correlation Coefficient

Hypothesis Testing for the Mean (Covariance is Known)

In the univariate case, the difference between the sample mean and the population mean is normally distributed. We consider

$$z = \frac{\sqrt{N}}{\sigma}(\bar{x} - \mu_0).$$

What about multivariate case?

Hypothesis Testing for the Mean (Covariance is Known)

Let $\mathbf{x}_1, \dots, \mathbf{x}_N$ constitute a sample from $\mathcal{N}_p(\boldsymbol{\mu}, \boldsymbol{\Sigma})$.

What about multivariate case to test $\boldsymbol{\mu} = \boldsymbol{\mu}_0$?

$$\frac{\sqrt{N}}{\sigma}(\bar{x} - \mu_0) \implies \frac{N}{\sigma^2}(\bar{x} - \mu_0)^2 \implies N(\bar{\mathbf{x}} - \boldsymbol{\mu}_0)^\top \boldsymbol{\Sigma}^{-1}(\bar{\mathbf{x}} - \boldsymbol{\mu}_0).$$

Rejection Region

Let $\chi_p^2(\alpha)$ be the number such that

$$\Pr \left\{ N(\bar{\mathbf{x}} - \boldsymbol{\mu})^\top \boldsymbol{\Sigma}^{-1} (\bar{\mathbf{x}} - \boldsymbol{\mu}) > \chi_p^2(\alpha) \right\} = \alpha.$$

To test the hypothesis that $\boldsymbol{\mu} = \boldsymbol{\mu}_0$ where $\boldsymbol{\mu}_0$ is a specified vector, we use as our rejection region (critical region)

$$N(\bar{\mathbf{x}} - \boldsymbol{\mu}_0)^\top \boldsymbol{\Sigma}^{-1} (\bar{\mathbf{x}} - \boldsymbol{\mu}_0) > \chi_p^2(\alpha).$$

If above inequality is satisfied, we reject the null hypothesis.

Consider the statement made on the basis of a sample with mean $\bar{\mathbf{x}}$:
“The mean of the distribution satisfies

$$N(\bar{\mathbf{x}} - \boldsymbol{\mu}^*)^\top \boldsymbol{\Sigma}^{-1}(\bar{\mathbf{x}} - \boldsymbol{\mu}^*) \leq \chi_p^2(\alpha).$$

as an inequality on $\boldsymbol{\mu}^*$.” This statement is true with probability $1 - \alpha$.

Thus, the set of $\boldsymbol{\mu}^*$ satisfying above inequality is a confidence region for $\boldsymbol{\mu}$ with confidence $1 - \alpha$.

Two-Sample Problems

Suppose there are two samples:

- ① $\mathbf{x}_1^{(1)}, \dots, \mathbf{x}_{N_1}^{(1)}$ from $\mathcal{N}(\boldsymbol{\mu}^{(1)}, \boldsymbol{\Sigma})$;
- ② $\mathbf{x}_1^{(2)}, \dots, \mathbf{x}_{N_2}^{(2)}$ from $\mathcal{N}(\boldsymbol{\mu}^{(2)}, \boldsymbol{\Sigma})$;

where $\boldsymbol{\Sigma}$ is known.

How to test the hypothesis $\boldsymbol{\mu}^{(1)} = \boldsymbol{\mu}^{(2)}$?

- 1 Noncentral Chi-Squared Distribution
- 2 Hypothesis Testing for the Mean (Covariance is Known)
- 3 Sample Correlation Coefficient

Sample Correlation Coefficient

Given the sample $\mathbf{x}_1, \dots, \mathbf{x}_N$ from $\mathcal{N}_p(\boldsymbol{\mu}, \boldsymbol{\Sigma})$, the maximum likelihood estimator of the correlation between the i -th and the j -th components is

$$r_{ij} = \frac{\sum_{\alpha=1}^N (x_{i\alpha} - \bar{x}_i)(x_{j\alpha} - \bar{x}_j)}{\sqrt{\sum_{\alpha=1}^N (x_{i\alpha} - \bar{x}_i)^2} \sqrt{\sum_{\alpha=1}^N (x_{j\alpha} - \bar{x}_j)^2}},$$

where $x_{i\alpha}$ is the i -th component of \mathbf{x}_α and

$$\bar{x}_i = \frac{1}{N} \sum_{\alpha=1}^N x_{i\alpha}.$$

We shall find the distribution of r_{ij} .

Sample Correlation Coefficient

If the population correlation

$$\rho_{ij} = \frac{\sigma_{ij}}{\sqrt{\sigma_{ii}\sigma_{jj}}}$$

is zero, then the density of sample correlation r_{ij} is

$$k_N(r) = \frac{\Gamma\left(\frac{N-1}{2}\right)}{\sqrt{\pi} \Gamma\left(\frac{N-2}{2}\right)} (1 - r^2)^{\frac{N-4}{2}}.$$
