The Density of Wishart Distribution

Theorem

The density of $\mathbf{A} \sim \mathcal{W}_p(\mathbf{\Sigma}, n)$ is

$$w_p(\mathbf{A} \mid \mathbf{\Sigma}, n) = \frac{(\det(\mathbf{A}))^{\frac{n-p-1}{2}} \exp\left(-\frac{1}{2}\text{tr}(\mathbf{\Sigma}^{-1}\mathbf{A})\right)}{2^{\frac{np}{2}} \pi^{\frac{p(p-1)}{4}} (\det(\mathbf{\Sigma}))^{\frac{n}{2}} \prod_{i=1}^p \Gamma\left(\frac{1}{2}(n+1-i)\right)}.$$

for positive definite \mathbf{A} and 0 elsewhere.

Sketch of the proof:

- 1 Observe that $\mathbf{B} = \mathbf{\Sigma}^{-1/2}\mathbf{A}\mathbf{\Sigma}^{-1/2} \sim \mathcal{W}_p(\mathbf{I}_p, n)$.
- 2 Find the density of $\mathbf{B} \sim \mathcal{W}_p(\mathbf{I}_p, n)$ by induction.
- 3 Recall that the Jacobian of transform from \mathbf{A} to \mathbf{B} has determinant

$$(\det(\mathbf{\Sigma}^{-1/2}))^{p+1} = (\det(\mathbf{\Sigma}))^{-\frac{p+1}{2}}.$$

- 4 Achieve the density of $\mathbf{A} \sim \mathcal{W}_p(\mathbf{\Sigma}, n)$.

The Wishart Distribution

The multivariate gamma function is defined as

$$\Gamma_p(t) = \pi^{\frac{p(p-1)}{4}} \prod_{i=1}^p \Gamma\left(t - \frac{1}{2}(i-1)\right).$$

We also write the density function of Wishart distribution as

$$w_p(\mathbf{A} \mid \mathbf{\Sigma}, n) = \frac{(\det(\mathbf{A}))^{\frac{n-p-1}{2}} \exp\left(-\frac{1}{2}\text{tr}(\mathbf{\Sigma}^{-1}\mathbf{A})\right)}{2^{\frac{np}{2}} \Gamma_p\left(\frac{n}{2}\right) (\det(\mathbf{\Sigma}))^{\frac{n}{2}}}.$$

Properties of Wishart Distribution

Let $\mathbf{A} \sim \mathcal{W}_p(\mathbf{\Sigma}, n)$ and partition \mathbf{A} and $\mathbf{\Sigma}$ into q and $p - q$ rows and columns as

$$\mathbf{A} = \begin{bmatrix} \mathbf{A}_{11} & \mathbf{A}_{12} \\ \mathbf{A}_{21} & \mathbf{A}_{22} \end{bmatrix} \quad \text{and} \quad \mathbf{\Sigma} = \begin{bmatrix} \mathbf{\Sigma}_{11} & \mathbf{\Sigma}_{12} \\ \mathbf{\Sigma}_{21} & \mathbf{\Sigma}_{22} \end{bmatrix},$$

then we have

(a) $\mathbf{A}_{11} \sim \mathcal{W}_q(\mathbf{\Sigma}_{11}, n)$ and $\mathbf{A}_{22} \sim \mathcal{W}_{p-q}(\mathbf{\Sigma}_{22}, n)$;

(b) if $q = 1$, then

$$\mathbf{a}_{21} \mid \mathbf{A}_{22} \sim \mathcal{N}_{p-q}(\mathbf{A}_{22} \mathbf{\Sigma}_{22}^{-1} \sigma_{21}, \sigma_{11.2}^2 \mathbf{A}_{22})$$

where $\sigma_{11.2}^2 = \sigma_{11} - \sigma_{21}^\top \mathbf{\Sigma}_{22}^{-1} \sigma_{21}$;

(c) if $n > p - q$, then

$$\mathbf{A}_{11.2} = \mathbf{A}_{11} - \mathbf{A}_{12} \mathbf{A}_{22}^{-1} \mathbf{A}_{21} \sim \mathcal{W}_q(\mathbf{\Sigma}_{11.2}, n - p + q)$$

is independent on \mathbf{A}_{22} and \mathbf{A}_{12} , where $\mathbf{\Sigma}_{11.2} = \mathbf{\Sigma}_{11} - \mathbf{\Sigma}_{12} \mathbf{\Sigma}_{22}^{-1} \mathbf{\Sigma}_{21}$.

1 The Density of Wishart Distribution

2 T^2 -Statistic and F -Distribution

3 The Inverted Wishart Distribution

The Distribution of Sample Covariance

Recall that we define

$$\mathbf{A} = \sum_{\alpha=1}^N (\mathbf{x}_{\alpha} - \bar{\mathbf{x}})(\mathbf{x}_{\alpha} - \bar{\mathbf{x}})^{\top} \quad \text{and} \quad \mathbf{S} = \frac{1}{n} \sum_{\alpha=1}^N (\mathbf{x}_{\alpha} - \bar{\mathbf{x}})(\mathbf{x}_{\alpha} - \bar{\mathbf{x}})^{\top}$$

where $\mathbf{x}_1, \dots, \mathbf{x}_N$ are independent, each with the distribution $\mathcal{N}_p(\boldsymbol{\mu}, \boldsymbol{\Sigma})$,
and $n = N - 1 \geq p$.

We have $\mathbf{A} \sim \mathcal{W}_p(\boldsymbol{\Sigma}, n)$, then

$$\mathbf{S} \sim \mathcal{W}_p\left(\frac{1}{n}\boldsymbol{\Sigma}, n\right)$$

In hypothesis testing for the mean with unknown variance, we consider the t -student variable

$$t = \frac{\bar{x} - \mu}{s/\sqrt{N}},$$

$$\text{where } \bar{x} = \frac{1}{N} \sum_{\alpha=1}^N x_{\alpha} \text{ and } s^2 = \frac{1}{N-1} \sum_{\alpha=1}^N (x_{\alpha} - \bar{x})^2.$$

We have $t^2 = \frac{N(\bar{x} - \mu)^2}{s^2}$ and its multivariate analog is

$$T^2 = N(\bar{\mathbf{x}} - \boldsymbol{\mu})^{\top} \mathbf{S}^{-1} (\bar{\mathbf{x}} - \boldsymbol{\mu}),$$

$$\text{where } \bar{\mathbf{x}} = \frac{1}{N} \sum_{\alpha=1}^N \mathbf{x}_{\alpha} \text{ and } \mathbf{S} = \frac{1}{N-1} \sum_{\alpha=1}^N (\mathbf{x}_{\alpha} - \bar{\mathbf{x}})(\mathbf{x}_{\alpha} - \bar{\mathbf{x}})^{\top}.$$

The F -distribution with d_1 and d_2 degrees of freedom is the distribution of

$$z = \frac{y_1/d_1}{y_2/d_2} = \frac{d_2 y_1}{d_1 y_2},$$

where $y_1 \sim \chi_{d_1}^2$ and $y_2 \sim \chi_{d_2}^2$ are independent, written as

$$z \sim F_{d_1, d_2}.$$

F-Distribution

The density function of F -distribution is

$$f(z; d_1, d_2) = \frac{1}{B\left(\frac{d_1}{2}, \frac{d_2}{2}\right)} \left(\frac{d_1}{d_2}\right)^{\frac{d_1}{2}} z^{\frac{d_1}{2}-1} \left(1 + \frac{d_1 z}{d_2}\right)^{-\frac{d_1+d_2}{2}}$$

for $z > 0$, where $B(\alpha, \beta) = \int_0^1 t^{\alpha-1}(1-t)^{\beta-1} dt$.

T^2 -Statistic and F -Distribution

Theorem

Let $\mathbf{A} \sim \mathcal{W}_p(\boldsymbol{\Sigma}, n)$ and $\mathbf{y} \sim \mathcal{N}_p(\mathbf{0}, \boldsymbol{\Sigma})$ be independent with $n \geq p$, then

$$\frac{n-p+1}{p} \cdot \mathbf{y}^\top \mathbf{A}^{-1} \mathbf{y} \sim F_{p, n-p+1}.$$

For T^2 -statistic

$$T^2 = N(\bar{\mathbf{x}} - \boldsymbol{\mu})^\top \mathbf{S}^{-1}(\bar{\mathbf{x}} - \boldsymbol{\mu}),$$

we have

$$\frac{N-p}{(N-1)p} \cdot T^2 \sim F_{p, n-p+1}.$$

Outline

- 1 The Density of Wishart Distribution
- 2 T^2 -Statistic and F -Distribution
- 3 The Inverted Wishart Distribution

The Inverted Wishart Distribution

If $\mathbf{A} \sim \mathcal{W}_p(\mathbf{\Sigma}, m)$, then $\mathbf{B} = \mathbf{A}^{-1}$ has the inverted Wishart distribution with m degrees of freedom and scale parameter $\mathbf{\Psi} = \mathbf{\Sigma}^{-1}$, written as

$$\mathbf{B} \sim \mathcal{W}_p^{-1}(\mathbf{\Psi}, m).$$

The density function of \mathbf{B} is

$$w^{-1}(\mathbf{B} \mid \mathbf{\Psi}, m) = \frac{(\det(\mathbf{\Psi}))^{\frac{m}{2}} (\det(\mathbf{B}))^{-\frac{m+p+1}{2}} \exp\left(-\frac{1}{2}\text{tr}(\mathbf{\Psi}\mathbf{B}^{-1})\right)}{2^{\frac{mp}{2}} \Gamma_p\left(\frac{m}{2}\right)},$$

where

$$\Gamma_p(t) = \pi^{\frac{p(p-1)}{4}} \prod_{i=1}^p \Gamma\left(t - \frac{1}{2}(i-1)\right).$$

Define $\bar{\mathbb{S}}^p \rightarrow \mathbb{R}^{p \times p}$ as

$$\mathbf{F}(\mathbf{X}) = \mathbf{X}^{-1},$$

where $\bar{\mathbb{S}}^p = \{\mathbf{X} \in \mathbb{R}^{p \times p} : \mathbf{X} = \mathbf{X}^\top \text{ and } \mathbf{X} \text{ is non-singular}\}$.

What is the determinant of Jacobian of $\mathbf{F}(\mathbf{X})$?

Let $\mathbf{x} \sim \mathcal{N}_p(\boldsymbol{\mu}, \boldsymbol{\Sigma})$. We define $\boldsymbol{\Psi} = \boldsymbol{\Sigma}^{-1}$ as the precision matrix.

① It is well-known that

$\sigma_{ij} = 0$ if and only if x_i and x_j are independent.

② What is the meaning of $\psi_{ij} = 0$?
