# Random Vectors and Matrices

- ① A random matrix (vector) is a matrix (vector) whose elements are random variables.
- ② The expected value of a random matrix (or vector) is the matrix (vector) consisting of the expected values of each of its elements.
- ③ Let  $\mathbf{X}$  be an  $m \times n$  random matrix, then its expected value, denoted by  $\mathbb{E}[\mathbf{X}]$ , is the  $m \times n$  matrix of numbers (if they exist)

$$\mathbb{E}[\mathbf{X}] = \begin{bmatrix} \mathbb{E}[x_{11}] & \mathbb{E}[x_{12}] & \dots & \mathbb{E}[x_{1n}] \\ \mathbb{E}[x_{21}] & \mathbb{E}[x_{22}] & \dots & \mathbb{E}[x_{2n}] \\ \vdots & \vdots & \ddots & \vdots \\ \mathbb{E}[x_{m1}] & \mathbb{E}[x_{m2}] & \dots & \mathbb{E}[x_{mn}] \end{bmatrix}.$$

# Expectation of Random Matrices

Let  $\mathbf{X}$  and  $\mathbf{Y}$  be random matrices of the same dimension, and let  $\mathbf{A}$  and  $\mathbf{B}$  be conformable matrices of constants. Then we have

$$\mathbb{E}[\mathbf{X} + \mathbf{Y}] = \mathbb{E}[\mathbf{X}] + \mathbb{E}[\mathbf{Y}]$$

and

$$\mathbb{E}[\mathbf{AXB}] = \mathbf{A}\mathbb{E}[\mathbf{X}]\mathbf{B}.$$

# Random Vector and Covariance Matrix

For random vector  $\mathbf{x} = [x_1, \dots, x_p]^\top$ , we denote  $\boldsymbol{\mu} = \mathbb{E}[\mathbf{x}]$ .

The expected value of the random matrix  $(\mathbf{x} - \boldsymbol{\mu})(\mathbf{x} - \boldsymbol{\mu})^\top$  is

$$\text{Cov}[\mathbf{x}] = \mathbb{E} \left[ (\mathbf{x} - \boldsymbol{\mu})(\mathbf{x} - \boldsymbol{\mu})^\top \right],$$

the covariance or covariance matrix of  $\mathbf{x}$ .

- 1 The  $i$ -th diagonal element of this matrix,  $\mathbb{E}[(x_i - \mu_i)^2]$ , is the variance of  $x_i$ .
- 2 The  $i, j$ -th off-diagonal element ( $i \neq j$ ),  $\mathbb{E}[(x_i - \mu_i)(x_j - \mu_j)]$  is the covariance of  $x_i$  and  $x_j$ .
- 3 We have  $\text{Cov}[\mathbf{x}] = \mathbb{E}[\mathbf{x}\mathbf{x}^\top] - \boldsymbol{\mu}\boldsymbol{\mu}^\top$ .

# Outline

- 3 Generalized Variance
- 4 Multivariate Normal Distribution

## Theorem

Let  $\mathbf{y} = \mathbf{D}\mathbf{x} + \mathbf{f}$ , where

- ①  $\mathbf{D}$  is an  $n \times p$  constant matrix,
- ②  $\mathbf{x}$  is a  $p$ -dimensional random vector,
- ③ and  $\mathbf{f}$  is a  $n$ -dimensional constant vector.

Then we have

$$\mathbb{E}[\mathbf{y}] = \mathbf{D}\mathbb{E}[\mathbf{x}] + \mathbf{f} \quad \text{and} \quad \text{Cov}[\mathbf{y}] = \text{Cov}[\mathbf{D}\mathbf{x}] = \mathbf{D}\text{Cov}[\mathbf{x}]\mathbf{D}^T.$$

# Example

Let  $\mathbf{x} = [x_1, x_2]^\top$  be a random vector with

$$\mathbb{E}[\mathbf{x}] = \begin{bmatrix} \mu_1 \\ \mu_2 \end{bmatrix} \quad \text{and} \quad \text{Cov}[\mathbf{x}] = \begin{bmatrix} \sigma_{11} & \sigma_{12} \\ \sigma_{21} & \sigma_{22} \end{bmatrix}.$$

Let  $\mathbf{z} = [z_1, z_2]$  such that  $z_1 = x_1 - x_2$  and  $z_2 = x_1 + x_2$ .

- 1 Find the  $\mathbb{E}[\mathbf{z}]$  and  $\text{Cov}[\mathbf{z}]$ .
- 2 Find the condition that leads to  $z_1$  and  $z_2$  be uncorrelated.

For random vector  $\mathbf{x} = [x_1, \dots, x_p]^\top$ , we write its covariance as

$$\text{Cov}[\mathbf{x}] = \mathbf{\Sigma} = \begin{bmatrix} \sigma_{11} & \dots & \sigma_{1p} \\ \vdots & \ddots & \vdots \\ \sigma_{p1} & \dots & \sigma_{pp} \end{bmatrix}.$$

The correlation coefficient  $\rho_{ij}$  is defined as

$$\rho_{ij} = \frac{\sigma_{ij}}{\sqrt{\sigma_{ii}\sigma_{jj}}},$$

which measures linear association between  $x_i$  and  $x_j$ .

The population correlation matrix of  $\mathbf{x}$  is defined as

$$\begin{aligned}\boldsymbol{\rho} &= \begin{bmatrix} \frac{\sigma_{11}}{\sqrt{\sigma_{11}\sigma_{11}}} & \cdots & \frac{\sigma_{1p}}{\sqrt{\sigma_{11}\sigma_{pp}}} \\ \vdots & \ddots & \vdots \\ \frac{\sigma_{p1}}{\sqrt{\sigma_{pp}\sigma_{11}}} & \cdots & \frac{\sigma_{pp}}{\sqrt{\sigma_{pp}\sigma_{pp}}} \end{bmatrix} \\ &= \begin{bmatrix} 1 & \cdots & \rho_{1p} \\ \vdots & \ddots & \vdots \\ \rho_{p1} & \cdots & 1 \end{bmatrix}.\end{aligned}$$

# Transformation of Variables

Let the density of  $p$ -dimensional random vector  $\mathbf{x} = [x_1, \dots, x_p]^\top$  be  $f(\mathbf{x})$ .

Consider the  $p$ -dimensional random vector  $\mathbf{y} = [y_1, \dots, y_p]^\top$  such that  $y_i = u_i(\mathbf{x})$  for  $i = 1, \dots, p$ . Let the density function of  $\mathbf{y}$  be  $g(\mathbf{y})$ .

Assume the transformation  $\mathbf{u}(\mathbf{x}) = [u_1(\mathbf{x}), \dots, u_p(\mathbf{x})]^\top : \mathbb{R}^p \rightarrow \mathbb{R}^p$  from the space of  $\mathbf{x}$  to the space of  $\mathbf{y}$  is smooth and one-to-one.

Then we have  $f(\mathbf{x}) = g(\mathbf{u}(\mathbf{x})) |\det(\mathbf{J}(\mathbf{x}))|$  where

$$\mathbf{J}(\mathbf{x}) = \begin{bmatrix} \frac{\partial u_1(\mathbf{x})}{\partial x_1} & \frac{\partial u_1(\mathbf{x})}{\partial x_2} & \dots & \frac{\partial u_1(\mathbf{x})}{\partial x_p} \\ \frac{\partial u_2(\mathbf{x})}{\partial x_1} & \frac{\partial u_2(\mathbf{x})}{\partial x_2} & \dots & \frac{\partial u_2(\mathbf{x})}{\partial x_p} \\ \vdots & \vdots & \ddots & \vdots \\ \frac{\partial u_p(\mathbf{x})}{\partial x_1} & \frac{\partial u_p(\mathbf{x})}{\partial x_2} & \dots & \frac{\partial u_p(\mathbf{x})}{\partial x_p} \end{bmatrix}.$$

# Transformation of Variables

Similarly, we also have  $g(\mathbf{y}) = f(\mathbf{u}^{-1}(\mathbf{y})) |\det(\mathbf{J}^{-1}(\mathbf{y}))|$  where

$$\mathbf{J}^{-1}(\mathbf{y}) = \begin{bmatrix} \frac{\partial u_1^{-1}(\mathbf{y})}{\partial y_1} & \frac{\partial u_1^{-1}(\mathbf{y})}{\partial y_2} & \cdots & \frac{\partial u_1^{-1}(\mathbf{y})}{\partial y_p} \\ \frac{\partial u_2^{-1}(\mathbf{y})}{\partial y_1} & \frac{\partial u_2^{-1}(\mathbf{y})}{\partial y_2} & \cdots & \frac{\partial u_2^{-1}(\mathbf{y})}{\partial y_p} \\ \vdots & \vdots & \ddots & \vdots \\ \frac{\partial u_p^{-1}(\mathbf{y})}{\partial y_1} & \frac{\partial u_p^{-1}(\mathbf{y})}{\partial y_2} & \cdots & \frac{\partial u_p^{-1}(\mathbf{y})}{\partial y_p} \end{bmatrix}.$$

# Random Samples

We use the notation  $x_{\alpha j}$  to indicate the value of the  $\alpha$ -th variable that is observed on the  $j$ -th item, or trial.

We display the  $N$  measurements on  $p$  variables as the  $N \times p$  matrix

$$\mathbf{X} = \begin{bmatrix} x_{11} & x_{12} & \dots & x_{1j} & \dots & x_{1p} \\ x_{21} & x_{22} & \dots & x_{2j} & \dots & x_{2p} \\ \vdots & \vdots & \ddots & \vdots & \ddots & \vdots \\ x_{\alpha 1} & x_{\alpha 2} & \dots & x_{\alpha j} & \dots & x_{\alpha p} \\ \vdots & \vdots & \ddots & \vdots & \ddots & \vdots \\ x_{N1} & x_{N2} & \dots & x_{Nj} & \dots & x_{Np} \end{bmatrix} = \begin{bmatrix} \mathbf{x}_1^\top \\ \mathbf{x}_2^\top \\ \vdots \\ \mathbf{x}_i^\top \\ \vdots \\ \mathbf{x}_N^\top \end{bmatrix}.$$

We mainly focus on the following case.

- 1 The independence of measurements from trial to trial may not hold when the variables are likely to drift over time.

# Sample Mean and Covariance

Let  $\mathbf{x}_1, \dots, \mathbf{x}_N$  be a random sample from a joint distribution that has mean vector  $\boldsymbol{\mu}$ , and covariance matrix  $\boldsymbol{\Sigma}$ . Then the sample means

$$\hat{\boldsymbol{\mu}} = \bar{\mathbf{x}} = \frac{1}{N} \sum_{\alpha=1}^N \mathbf{x}_{\alpha}$$

is an unbiased estimator of  $\boldsymbol{\mu}$ , and its covariance matrix is

$$\text{Cov}[\bar{\mathbf{x}}] = \frac{1}{N} \boldsymbol{\Sigma}.$$

However, the matrix

$$\hat{\boldsymbol{\Sigma}} = \frac{1}{N} \sum_{\alpha=1}^N (\mathbf{x}_{\alpha} - \bar{\mathbf{x}})(\mathbf{x}_{\alpha} - \bar{\mathbf{x}})^{\top}$$

is a biased estimator of  $\boldsymbol{\Sigma}$ .

# Sample Covariance

We define the sample (variance-covariance) covariance matrix as

$$\mathbf{S} = \frac{N}{N-1} \hat{\mathbf{\Sigma}} = \frac{1}{N-1} \sum_{\alpha=1}^N (\mathbf{x}_{\alpha} - \bar{\mathbf{x}})(\mathbf{x}_{\alpha} - \bar{\mathbf{x}})^{\top}, \quad (1)$$

which is an unbiased estimator of  $\mathbf{\Sigma}$ .

Let  $\mathbf{1}_N = [1, \dots, 1]^{\top} \in \mathbb{R}^N$ , then we have

$$\mathbf{S} = \frac{1}{N-1} \mathbf{X}^{\top} \left( \mathbf{I}_N - \frac{1}{N} \mathbf{1}_N \mathbf{1}_N^{\top} \right) \mathbf{X} \quad (2)$$

$$= \frac{1}{N-1} \left( \mathbf{X}^{\top} \mathbf{X} - \frac{1}{N} \mathbf{X}^{\top} \mathbf{1}_N \mathbf{1}_N^{\top} \mathbf{X} \right). \quad (3)$$

It provides a more efficient implementation.

# Sample Correlation

Given sample covariance matrix

$$\mathbf{S} = \begin{bmatrix} s_{11} & \cdots & s_{1p} \\ \vdots & \ddots & \vdots \\ s_{p1} & \cdots & s_{pp} \end{bmatrix} \in \mathbb{R}^{p \times p},$$

we define the sample correlation matrix as

$$\mathbf{R} = \begin{bmatrix} r_{11} & \cdots & r_{1p} \\ \vdots & \ddots & \vdots \\ r_{p1} & \cdots & r_{pp} \end{bmatrix} \in \mathbb{R}^{p \times p},$$

$$\text{where } r_{ij} = \frac{s_{ij}}{\sqrt{s_{ii}}\sqrt{s_{jj}}}.$$

# Geometrical Interpretation

We display  $p$ -dimensional random vectors  $\mathbf{x}_1, \dots, \mathbf{x}_N$  as follows

$$\mathbf{X} = \begin{bmatrix} x_{11} & \dots & x_{1p} \\ \vdots & \ddots & \vdots \\ x_{N1} & \dots & x_{Np} \end{bmatrix} = \begin{bmatrix} \mathbf{x}_1^\top \\ \vdots \\ \mathbf{x}_N^\top \end{bmatrix} = [\mathbf{y}_1 \quad \dots \quad \mathbf{y}_p] \in \mathbb{R}^{N \times p}.$$

We denote  $\bar{\mathbf{x}} = [\bar{x}_1 \quad \dots \quad \bar{x}_p]^\top$  and  $\mathbf{d}_i = \mathbf{y}_i - \bar{x}_i \mathbf{1}_N$ .

- 1 The projection of  $\mathbf{y}_i$  onto the equal angular vector  $\mathbf{1}_N$  is the vector  $\bar{x}_i \mathbf{1}_N$ .
- 2 The information comprising  $\mathbf{S}$  is obtained from the deviation vectors  $\{\mathbf{d}_i\}$ .
- 3 The sample correlation  $r_{ij}$  is the cosine of the angle between  $\mathbf{d}_i$  and  $\mathbf{d}_j$ .

# Outline

- 1 Random Vectors and Matrices
- 2 Random Samples
- 3 Generalized Variance**
- 4 Multivariate Normal Distribution

# Sample Covariance

When all variables are observed, the variation is described by the sample covariance matrix

$$\mathbf{S} = \begin{bmatrix} s_{11} & s_{12} & \cdots & s_{1p} \\ s_{21} & s_{22} & \cdots & s_{2p} \\ \vdots & \vdots & \ddots & \vdots \\ s_{p1} & s_{p2} & \cdots & s_{pp} \end{bmatrix} \in \mathbb{R}^{p \times p},$$

where  $s_{ij} = \frac{1}{N-1} \sum_{\alpha=1}^N (x_{\alpha i} - \bar{x}_i)(x_{\alpha j} - \bar{x}_j).$

The sample covariance matrix contains  $p$  variances and  $p(p-1)/2$  potentially different covariances.

# Generalized Sample Variance

The value of  $\det(\mathbf{S})$  reduces to usual sample variance when  $p = 1$ .

This determinant is called the generalized sample variance:

$$\text{generalized sample variance} = \det(\mathbf{S}).$$

# Geometrical Interpretation: Parallelotope

## Theorem

Define  $\mathbf{V} = [\mathbf{v}_1, \dots, \mathbf{v}_p] \in \mathbb{R}^{N \times p}$  and let

$$\text{Vol}(\mathbf{v}_1, \dots, \mathbf{v}_p)$$

be the  $p$ -dimensional volume of the parallelotope with  $\mathbf{v}_1, \dots, \mathbf{v}_p \in \mathbb{R}^N$  as principal edges ( $N \geq p$ ), then

$$(\text{Vol}(\mathbf{v}_1, \dots, \mathbf{v}_p))^2 = \det(\mathbf{V}^\top \mathbf{V}).$$

For  $\mathbf{d}_i = \mathbf{y}_i - \bar{x}_i \mathbf{1}_N$ , we have

$$\det(\mathbf{S}) = (N - 1)^{-p} (\text{Vol}(\mathbf{d}_1, \dots, \mathbf{d}_p))^2.$$

# Geometrical Interpretation: Parallelotope

**Figure 3.6** (a) "Large" generalized sample variance for  $p = 3$ .  
(b) "Small" generalized sample variance for  $p = 3$ .

# Geometrical Interpretation: Hyperellipsoid

The coordinates

$$\mathbf{x} = [x_1, x_2, \dots, x_p]^\top$$

of the points a constant distance  $c > 0$  from  $\bar{\mathbf{x}}$  satisfy (suppose  $\mathbf{S} \succ \mathbf{0}$ )

$$(\mathbf{x} - \bar{\mathbf{x}})^\top \mathbf{S}^{-1} (\mathbf{x} - \bar{\mathbf{x}}) = c^2,$$

which defines hyperellipsoid centered at  $\bar{\mathbf{x}}$ .

The volume of this hyperellipsoid is

$$\frac{2\pi^{p/2}}{p\Gamma(p/2)} \cdot c^p (\det(\mathbf{S}))^{1/2},$$

where

$$\Gamma(p) = \int_0^\infty t^{p-1} \exp(-t) dt.$$

# Generalized Sample Variance is Zero

The generalized variance is zero when, and only when, at least one of

$$\{\mathbf{d}_1, \dots, \mathbf{d}_p\}$$

lies in the hyperplane formed by all linear combinations of the others.

That is, the columns of the matrix of deviations

$$\begin{aligned}\mathbf{X} - \mathbf{1}_N \bar{\mathbf{x}}^\top &= \begin{bmatrix} (\mathbf{x}_1 - \bar{\mathbf{x}})^\top \\ \vdots \\ (\mathbf{x}_N - \bar{\mathbf{x}})^\top \end{bmatrix} = [\mathbf{y}_1 - \bar{x}_1 \mathbf{1}_N \quad \dots \quad \mathbf{y}_p - \bar{x}_p \mathbf{1}_N] \\ &= [\mathbf{d}_1 \quad \dots \quad \mathbf{d}_p] \in \mathbb{R}^{N \times p}\end{aligned}$$

are linearly dependent.

# Generalized Sample Variance Determined by Correlation

We can also define generalized variance by

$$\det(\mathbf{R}),$$

where  $\mathbf{R}$  is the sample correlation matrix

$$\mathbf{R} = \begin{bmatrix} r_{11} & \cdots & r_{1p} \\ \vdots & \ddots & \vdots \\ r_{p1} & \cdots & r_{pp} \end{bmatrix} \in \mathbb{R}^{p \times p},$$

where  $r_{ij} = \frac{s_{ij}}{\sqrt{s_{ii}}\sqrt{s_{jj}}}.$

It holds that

$$\det(\mathbf{S}) = \det(\mathbf{R}) \prod_{i=1}^p s_{ii}.$$

# Total Sample Variance

We define the total sample variance as the sum of the diagonal elements of the sample covariance matrix, that is

$$\text{total sample variance} = \sum_{i=1}^p s_{ii}.$$

- ① It is the sum of the squared lengths of the  $p$  deviation vectors

$$\mathbf{d}_1 = \mathbf{y}_1 - \bar{x}_1 \mathbf{1}_N, \dots, \mathbf{d}_p = \mathbf{y}_p - \bar{x}_p \mathbf{1}_N$$

divided by  $n - 1$ .

- ② It pays no attention to the orientation of  $\mathbf{d}_i$ .

# Outline

- 1 Random Vectors and Matrices
- 2 Random Samples
- 3 Generalized Variance
- 4 Multivariate Normal Distribution

# Univariate Normal Distribution

A random variable  $x$  is normally distributed with mean  $\mu$  and standard deviation  $\sigma > 0$  can be written in the following notation

$$x \sim \mathcal{N}(\mu, \sigma).$$

The probability density function of univariate normal distribution is

$$f(x) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(x-\mu)^2}{2\sigma^2}\right).$$

# Bivariate Normal Density

Two bivariate normal distributions:

- (a)  $\sigma_1 = \sigma_2$  and  $\rho_{12} = 0$
- (b)  $\sigma_1 = \sigma_2$  and  $\rho_{12} = 0.75$

# The Central Limit Theorem

Let  $x_1, \dots, x_n$  be independent and identically distributed random variables with the same arbitrary distribution, mean  $\mu$ , and variance  $\sigma^2$ .

Let  $\bar{x}_n = \frac{1}{n} \sum_{i=1}^n x_i$ , then the random variable

$$z = \lim_{n \rightarrow \infty} \sqrt{n} \left( \frac{\bar{x}_n - \mu}{\sigma} \right)$$

is a standard normal distribution.

The standard normal distribution is a normal distribution with a mean of 0 and standard deviation of 1.

What about multivariate case?

# Multivariate Normal Distribution

The multivariate normal distribution of a  $p$ -dimensional random vector  $\mathbf{x} = [x_1, \dots, x_p]^\top$  can be written in the following notation:

$$\mathbf{x} \sim \mathcal{N}_p(\boldsymbol{\mu}, \boldsymbol{\Sigma})$$

or to make it explicitly known that  $\mathbf{x}$  is  $p$ -dimensional.

$$\mathbf{x} \sim \mathcal{N}(\boldsymbol{\mu}, \boldsymbol{\Sigma}),$$

with  $p$ -dimensional mean vector

$$\boldsymbol{\mu} = \mathbb{E}[\mathbf{x}] = \begin{bmatrix} \mathbb{E}[x_1] \\ \vdots \\ \mathbb{E}[x_p] \end{bmatrix} \in \mathbb{R}^p$$

and covariance matrix

$$\boldsymbol{\Sigma} = \mathbb{E} \left[ (\mathbf{x} - \boldsymbol{\mu})(\mathbf{x} - \boldsymbol{\mu})^\top \right] \in \mathbb{R}^{p \times p}.$$

# Multivariate Normal Distribution

The density function of univariate normal distribution is

$$f(x) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(x-\mu)^2}{2\sigma^2}\right),$$

where  $\mu$  is the mean and  $\sigma^2$  is the variance with  $\sigma > 0$ .

The density function of non-singular  $p$ -dimensional multivariate normal distribution is

$$f(\mathbf{x}) = \frac{1}{\sqrt{(2\pi)^p \det(\mathbf{\Sigma})}} \exp\left(-\frac{1}{2}(\mathbf{x} - \boldsymbol{\mu})^\top \mathbf{\Sigma}^{-1}(\mathbf{x} - \boldsymbol{\mu})\right),$$

where  $\boldsymbol{\mu} \in \mathbb{R}^p$  is the mean and  $\mathbf{\Sigma}$  is the  $p \times p$  (non-singular) covariance matrix.

# Density Function of Multivariate Normal Distribution

We generalize the form of pdf for univariate normal distribution

$$f(x) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(x-\mu)^2}{2\sigma^2}\right),$$

to the multivariate case

$$f(\mathbf{x}) = K \exp\left(-\frac{1}{2}(\mathbf{x} - \mathbf{b})^\top \mathbf{A}(\mathbf{x} - \mathbf{b})\right),$$

where  $\mathbf{A}$  is symmetric positive definite.

We can verify that if  $\mathbb{E}[\mathbf{x}] = \boldsymbol{\mu}$  and  $\text{Cov}[\mathbf{x}] = \boldsymbol{\Sigma}$ , then

$$K = \frac{1}{\sqrt{(2\pi)^p \det(\boldsymbol{\Sigma})}}, \quad \mathbf{b} = \boldsymbol{\mu} \quad \text{and} \quad \mathbf{A} = \boldsymbol{\Sigma}^{-1}.$$

# Multivariate Normal Distribution

If the density of a  $p$ -dimensional random vector  $\mathbf{x}$  is

$$K \exp \left( -\frac{1}{2} (\mathbf{x} - \mathbf{b})^\top \mathbf{A} (\mathbf{x} - \mathbf{b}) \right),$$

where  $\mathbf{A} \in \mathbb{R}^{p \times p}$  is symmetric positive definite, then  $\mathbb{E}[\mathbf{x}] = \mathbf{b}$  and  $\text{Cov}[\mathbf{x}] = \mathbf{A}^{-1}$ .

Conversely, given a vector  $\boldsymbol{\mu} \in \mathbb{R}^p$  and a positive definite matrix  $\boldsymbol{\Sigma} \in \mathbb{R}^{p \times p}$ , there is a multivariate normal density

$$n(\mathbf{x} \mid \boldsymbol{\mu}, \boldsymbol{\Sigma}) = \frac{1}{\sqrt{(2\pi)^p \det(\boldsymbol{\Sigma})}} \exp \left( -\frac{1}{2} (\mathbf{x} - \boldsymbol{\mu})^\top \boldsymbol{\Sigma}^{-1} (\mathbf{x} - \boldsymbol{\mu}) \right).$$
