Outline

1 Multivariate Normal Distribution (Conditional Distribution)

Characteristic Function

3 Maximum Likelihood Estimator of Mean and Covariance

Let \mathbf{x} be distributed according to $\mathcal{N}_p(\mu, \mathbf{\Sigma})$ with $\mathbf{\Sigma} \succ \mathbf{0}$. Let us partition

$$\mathbf{x} = egin{bmatrix} \mathbf{x}^{(1)} \\ \mathbf{x}^{(2)} \end{bmatrix} \quad \text{with } \mathbf{x}^{(1)} \in \mathbb{R}^q \text{ and } \mathbf{x}^{(2)} \in \mathbb{R}^{p-q}.$$

The joint density of $\mathbf{y}^{(1)} = \mathbf{x}^{(1)} - \mathbf{\Sigma}_{12}\mathbf{\Sigma}_{22}^{-1}\mathbf{x}^{(2)}$ and $\mathbf{y}^{(2)} = \mathbf{x}^{(2)}$ is

$$g(\mathbf{y}) = n(\mathbf{y}^{(1)} \mid \boldsymbol{\mu}^{(1)} - \boldsymbol{\Sigma}_{12} \boldsymbol{\Sigma}_{22}^{-1} \boldsymbol{\mu}^{(2)}, \boldsymbol{\Sigma}_{11} - \boldsymbol{\Sigma}_{12} \boldsymbol{\Sigma}_{22}^{-1} \boldsymbol{\Sigma}_{21}) n(\mathbf{y}^{(2)} \mid \boldsymbol{\mu}^{(2)}, \boldsymbol{\Sigma}_{22}).$$

Consider that

$$\begin{bmatrix} \textbf{y}^{(1)} \\ \textbf{y}^{(2)} \end{bmatrix} = \begin{bmatrix} \textbf{I} & -\boldsymbol{\Sigma}_{12}\boldsymbol{\Sigma}_{22}^{-1} \\ \textbf{0} & \textbf{I} \end{bmatrix} \begin{bmatrix} \textbf{x}^{(1)} \\ \textbf{x}^{(2)} \end{bmatrix} = \textbf{u}(\textbf{x})$$

and use

$$f(\mathbf{x}) = g(\mathbf{u}(\mathbf{x}))|\det(\mathbf{J}(\mathbf{x}))| = g(\mathbf{u}(\mathbf{x})).$$

The resulting joint density of $\mathbf{x}^{(1)}$ and $\mathbf{x}^{(2)}$ is

$$\begin{split} f(\mathbf{x}) &= f(\mathbf{x}^{(1)}, \mathbf{x}^{(2)}) \\ &= n(\mathbf{y}^{(1)} \mid \boldsymbol{\mu}^{(1)} - \boldsymbol{\Sigma}_{12} \boldsymbol{\Sigma}_{22}^{-1} \boldsymbol{\mu}^{(2)}, \boldsymbol{\Sigma}_{11} - \boldsymbol{\Sigma}_{12} \boldsymbol{\Sigma}_{22}^{-1} \boldsymbol{\Sigma}_{21}) n(\mathbf{x}^{(2)} \mid \boldsymbol{\mu}^{(2)}, \boldsymbol{\Sigma}_{22}) \\ &= \frac{1}{\sqrt{(2\pi)^q \det(\boldsymbol{\Sigma}_{11.2})}} \exp\left(-\frac{1}{2} \left(\mathbf{x}_{11.2} - \boldsymbol{\mu}_{11.2}\right)^\top \boldsymbol{\Sigma}_{11.2}^{-1} \left(\mathbf{x}_{11.2} - \boldsymbol{\mu}_{11.2}\right)\right) \\ &\cdot \frac{1}{\sqrt{(2\pi)^{p-q} \det(\boldsymbol{\Sigma}_{22})}} \exp\left(-\frac{1}{2} \left(\mathbf{x}^{(2)} - \boldsymbol{\mu}^{(2)}\right)^\top \boldsymbol{\Sigma}_{22}^{-1} \left(\mathbf{x}^{(2)} - \boldsymbol{\mu}^{(2)}\right)\right) \end{split}$$

where

$$\begin{aligned} \mathbf{x}_{11.2} = & \mathbf{x}^{(1)} - \mathbf{\Sigma}_{12} \mathbf{\Sigma}_{22}^{-1} \mathbf{x}^{(2)}, \\ \boldsymbol{\mu}_{11.2} = & \boldsymbol{\mu}^{(1)} - \mathbf{\Sigma}_{12} \mathbf{\Sigma}_{22}^{-1} \boldsymbol{\mu}^{(2)}, \\ \mathbf{\Sigma}_{11.2} = & \mathbf{\Sigma}_{11} - \mathbf{\Sigma}_{12} \mathbf{\Sigma}_{22}^{-1} \mathbf{\Sigma}_{21}. \end{aligned}$$

The marginal density of $\mathbf{x}^{(2)}$ is

$$\begin{split} & f(\mathbf{x}^{(2)}) = n(\mathbf{y}^{(2)} \mid \boldsymbol{\mu}^{(2)}, \boldsymbol{\Sigma}_{22}) \\ = & \frac{1}{\sqrt{(2\pi)^{p-q} \det(\boldsymbol{\Sigma}_{22})}} \exp\left(-\frac{1}{2} \left(\mathbf{x}^{(2)} - \boldsymbol{\mu}^{(2)}\right)^{\top} \boldsymbol{\Sigma}_{22}^{-1} \left(\mathbf{x}^{(2)} - \boldsymbol{\mu}^{(2)}\right)\right). \end{split}$$

Hence, the conditional density of $\mathbf{x}^{(1)}$ given that $\mathbf{x}^{(2)}$ is

$$\begin{split} f(\mathbf{x}^{(1)} \mid \mathbf{x}^{(2)}) &= \frac{f(\mathbf{x}^{(1)}, \mathbf{x}^{(2)})}{f(\mathbf{x}^{(2)})} \\ &= \frac{1}{\sqrt{(2\pi)^q \det(\mathbf{\Sigma}_{11.2})}} \exp\left(-\frac{1}{2} \left(\mathbf{x}_{11.2} - \boldsymbol{\mu}_{11.2}\right)^\top \mathbf{\Sigma}_{11.2}^{-1} \left(\mathbf{x}_{11.2} - \boldsymbol{\mu}_{11.2}\right)\right) \end{split}$$

The conditional density of $\mathbf{x}^{(1)}$ given that $\mathbf{x}^{(2)}$ is

$$\begin{split} f(\mathbf{x}^{(1)} \mid \mathbf{x}^{(2)}) &= \frac{f(\mathbf{x}^{(1)}, \mathbf{x}^{(2)})}{f(\mathbf{x}^{(2)})} \\ &= \frac{1}{\sqrt{(2\pi)^q \det(\mathbf{\Sigma}_{11.2})}} \exp\left(-\frac{1}{2} \left(\mathbf{x}_{11.2} - \boldsymbol{\mu}_{11.2}\right)^\top \mathbf{\Sigma}_{11.2}^{-1} \left(\mathbf{x}_{11.2} - \boldsymbol{\mu}_{11.2}\right)\right) \end{split}$$

Consider that $\mathbf{x}_{11.2} - \boldsymbol{\mu}_{11.2} = \mathbf{x}^{(1)} - (\boldsymbol{\mu}^{(1)} + \boldsymbol{\Sigma}_{12} \boldsymbol{\Sigma}_{22}^{-1} (\mathbf{x}^{(2)} - \boldsymbol{\mu}^{(2)}))$.

The density $f(\mathbf{x}^{(1)} | \mathbf{x}^{(2)})$ is a q-variate normal density with mean

$$\mathbb{E}\big[\mathbf{x}^{(1)} \mid \mathbf{x}^{(2)}\big] = \boldsymbol{\mu}^{(1)} + \boldsymbol{\Sigma}_{12}\boldsymbol{\Sigma}_{22}^{-1}(\mathbf{x}^{(2)} - \boldsymbol{\mu}^{(2)}) = \boldsymbol{\nu}(\mathbf{x}^{(2)})$$

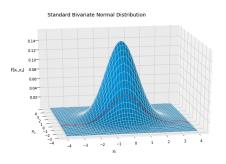

and covariance matrix (not depend on $\mathbf{x}^{(2)}$)

$$\begin{split} \operatorname{Cov} \big[\boldsymbol{x}^{(1)} \mid \boldsymbol{x}^{(2)} \big] = & \mathbb{E} \big[(\boldsymbol{x}^{(1)} - \boldsymbol{\nu}(\boldsymbol{x}^{(2)})) (\boldsymbol{x}^{(1)} - \boldsymbol{\nu}(\boldsymbol{x}^{(2)}))^{\top} \mid \boldsymbol{x}^{(2)} \big] \\ = & \boldsymbol{\Sigma}_{11.2} = \boldsymbol{\Sigma}_{11} - \boldsymbol{\Sigma}_{12} \boldsymbol{\Sigma}_{22}^{-1} \boldsymbol{\Sigma}_{21} \preceq \boldsymbol{\Sigma}_{11}. \end{split}$$

The density $f(x_1, x_2)$ can be thought of as a surface $z = f(x_1, x_2)$ over the x_1, x_2 -plane.

If we intersect this surface with the plane $x_2 = c$, we obtain a curve $z = f(x_1, c)$ over the line $x_2 = c$ in the x_1, x_2 -plane.

The ordinate of this curve is proportional to the conditional density of x_1 given $x_2 = c$; that is, it is proportional to the ordinate of the curve of a univariate normal distribution.

Correlation Coefficient

Recall that for random vector $\mathbf{x} = [x_1, x_2, \dots, x_p]^{\top}$, we define the covariance matrix as

$$\mathbf{\Sigma} = \begin{bmatrix} \sigma_{11} & \sigma_{12} & \dots & \sigma_{1p} \\ \sigma_{21} & \sigma_{22} & \dots & \sigma_{2p} \\ \vdots & \vdots & \ddots & \vdots \\ \sigma_{p1} & \sigma_{p2} & \dots & \sigma_{pp} \end{bmatrix} \in \mathbb{R}^{p \times p}$$

and the correlation coefficient between x_i and x_j as (suppose $\Sigma \succ 0$)

$$\rho_{ij} = \frac{\sigma_{ij}}{\sqrt{\sigma_{ii}}\sqrt{\sigma_{jj}}}.$$

Partial Correlation Coefficient

Now consider the partition

$$\mathbf{x} = egin{bmatrix} \mathbf{x}^{(1)} \\ \mathbf{x}^{(2)} \end{bmatrix}$$
 with $\mathbf{x}^{(1)} \in \mathbb{R}^q$ and $\mathbf{x}^{(2)} \in \mathbb{R}^{p-q}$.

Let

$$\mathbf{\Sigma}_{11.2} = \begin{bmatrix} \sigma_{11 \cdot q+1, \dots, p} & \sigma_{12 \cdot q+1, \dots, p} & \dots & \sigma_{1q \cdot q+1, \dots, p} \\ \sigma_{21 \cdot q+1, \dots, p} & \sigma_{22 \cdot q+1, \dots, p} & \dots & \sigma_{2q \cdot q+1, \dots, p} \\ \vdots & \vdots & \ddots & \vdots \\ \sigma_{q1 \cdot q+1, \dots, p} & \sigma_{q2 \cdot q+1, \dots, p} & \dots & \sigma_{qq \cdot q+1, \dots, p} \end{bmatrix} \in \mathbb{R}^{q \times q}.$$

We define

$$\rho_{ij\cdot q+1,\dots,p} = \frac{\sigma_{ij\cdot q+1,\dots,p}}{\sqrt{\sigma_{ii\cdot q+1,\dots,p}}\sqrt{\sigma_{jj\cdot q+1,\dots,p}}}$$

as the partial correlation between x_i and x_j holding x_{q+1}, \dots, x_p fixed.

We again consider $\mathbf{x} \sim \mathcal{N}_p(\boldsymbol{\mu}, \boldsymbol{\Sigma})$ such that

$$\mathbf{x} = \begin{bmatrix} \mathbf{x}^{(1)} \\ \mathbf{x}^{(2)} \end{bmatrix}, \quad \boldsymbol{\mu} = \begin{bmatrix} \boldsymbol{\mu}^{(1)} \\ \boldsymbol{\mu}^{(2)} \end{bmatrix} \quad \text{and} \quad \boldsymbol{\Sigma} = \begin{bmatrix} \boldsymbol{\Sigma}_{11} & \boldsymbol{\Sigma}_{12} \\ \boldsymbol{\Sigma}_{21} & \boldsymbol{\Sigma}_{22} \end{bmatrix} \succ \boldsymbol{0}.$$

Then, we study some properties of $\mathbf{Bx}^{(2)}$, where

$$\boldsymbol{\mathsf{B}} = \boldsymbol{\Sigma}_{12}\boldsymbol{\Sigma}_{22}^{-1}$$

is the matrix of regression coefficients of $\mathbf{x}^{(1)}$ on $\mathbf{x}^{(2)}$.

The vector $\mathbb{E}\big[\mathbf{x}^{(1)}\mid\mathbf{x}^{(2)}\big]=\boldsymbol{\mu}^{(1)}+\mathbf{B}(\mathbf{x}^{(2)}-\boldsymbol{\mu}^{(2)})$ is called the regression function.

The vector

$$\mathbf{x}^{(11.2)} = \mathbf{x}^{(1)} - (\boldsymbol{\mu}^{(1)} + \mathbf{B}(\mathbf{x}^{(2)} - \boldsymbol{\mu}^{(2)}))$$

is the vector of residuals of $\mathbf{x}^{(1)}$ from its regression on $\mathbf{x}^{(2)}$.

The components of $\mathbf{x}^{(11.2)}$ are uncorrelated with the components of $\mathbf{x}^{(2)}$ since we have

$$\mathbf{x}^{(11.2)} = \mathbf{y}^{(1)} - \mathbb{E}[\mathbf{y}^{(1)}],$$

such that

$$\begin{bmatrix} \textbf{y}^{(1)} \\ \textbf{y}^{(2)} \end{bmatrix} = \begin{bmatrix} \textbf{I} & -\boldsymbol{\Sigma}_{12}\boldsymbol{\Sigma}_{22}^{-1} \\ \textbf{0} & \textbf{I} \end{bmatrix} \begin{bmatrix} \textbf{x}^{(1)} \\ \textbf{x}^{(2)} \end{bmatrix} = \begin{bmatrix} \textbf{x}^{(1)} - \textbf{B}\textbf{x}^{(2)} \\ \textbf{x}^{(1)} \end{bmatrix}.$$

Theorem 1

For $\mathbf{x} \sim \mathcal{N}_p(\mu, \mathbf{\Sigma})$ and every vector $\alpha \in \mathbb{R}^{(p-q)}$, we have

$$\operatorname{Var}(x_i^{(11.2)}) \leq \operatorname{Var}(x_i - \boldsymbol{\alpha}^{\top} \mathbf{x}^{(2)}),$$

where $x_i^{(11.2)}$ and x_i are the *i*-th entry of $\mathbf{x}^{(11.2)}$ and the *i*-th entry of \mathbf{x} respectively.

Observe that

$$\mathbb{E}[\mathbf{x}_i] = \mu_i + \boldsymbol{\alpha}^{\top} (\mathbf{x}^{(2)} - \boldsymbol{\mu}^{(2)}),$$

which means

$$\mu_i + \boldsymbol{\beta}_{(i)}^{\top} (\mathbf{x}^{(2)} - \boldsymbol{\mu}^{(2)})$$

is the best linear predictor of x_i in all functions of the form $\alpha^{\top} \mathbf{x}^{(2)} + c$, the mean squared error of the above is a minimum.

The correlation of two variables z_1 and z_2 is defined as

$$\operatorname{Corr}(z_1, z_2) = \frac{\operatorname{Cov}[z_1, z_2]}{\sqrt{\operatorname{Var}[z_1]\operatorname{Var}[z_2]}}.$$

The maximum correlation between x_i and the linear combination $\alpha^{\top} \mathbf{x}^{(2)}$ is called the multiple correlation coefficient between x_i and $\alpha^{\top} \mathbf{x}^{(2)}$.

Corollary 1

Under the setting of Theorem 1, prove that

$$\operatorname{Corr}\left[x_{i}, \boldsymbol{\beta}_{(i)}^{\top} \mathbf{x}^{(2)}\right] \geq \operatorname{Corr}\left[x_{i}, \boldsymbol{\alpha}^{\top} \mathbf{x}^{(2)}\right]$$

for every $\alpha \in \mathbb{R}^{(p-q)}$.

Outline

Multivariate Normal Distribution (Conditional Distribution)

Characteristic Function

3 Maximum Likelihood Estimator of Mean and Covariance

The characteristic function of a p-dimensional random vector \mathbf{x} is

$$\phi(\mathbf{t}) = \mathbb{E}\left[\exp(\mathrm{i}\,\mathbf{t}^{\top}\mathbf{x})\right]$$

defined for every real vector $\mathbf{t} \in \mathbb{R}^p$.

For the complex-valued function g(z) be written as

$$g(z) = g_1(z) + i g_2(z),$$

where $g_1(z)$ and $g_2(z)$ are real-valued, the expected value of g(z) is

$$\mathbb{E}[g(z)] = \mathbb{E}[g_1(z)] + \mathrm{i}\,\mathbb{E}[g_2(z)].$$

Let $\mathbf{x} = \begin{bmatrix} \mathbf{x}^{(1)} \\ \mathbf{x}^{(2)} \end{bmatrix}$ be a p-dimensional random vector. If $\mathbf{x}^{(1)}$ and $\mathbf{x}^{(2)}$ are independent and $g(\mathbf{x}) = g^{(1)}(\mathbf{x}^{(1)})g^{(2)}(\mathbf{x}^{(2)})$, then we have $\mathbb{E}[g(\mathbf{x})] = \mathbb{E}[g^{(1)}(\mathbf{x}^{(1)})]\mathbb{E}[g^{(2)}(\mathbf{x}^{(2)})].$

If the components of \mathbf{x} are mutually independent, then

$$\mathbb{E} ig[\exp(\mathrm{i} \, \mathbf{t}^ op \mathbf{x}) ig] = \mathbb{E} \left[\prod_{j=1}^p \exp(\mathrm{i} \, t_j x_j)
ight].$$

Theorem 2

The characteristic function of ${\bf x}$ distributed according to $\mathcal{N}_p(\mu,{f \Sigma})$ is

$$\phi(\mathbf{t}) = \exp\left(\mathrm{i}\,\mathbf{t}^{ op}\boldsymbol{\mu} - \frac{1}{2}\mathbf{t}^{ op}\mathbf{\Sigma}\mathbf{t}\right).$$

for every $\mathbf{t} \in \mathbb{R}^p$.

Sketch of the proof

- **1** The characteristic function of $\mathbf{y} \sim \mathcal{N}_p(\mathbf{0}, \mathbf{I})$ is $\phi_0(\mathbf{t}) = \exp\left(-\frac{1}{2}\mathbf{t}^{\top}\mathbf{t}\right)$.
- ② For $\mathbf{x} \sim \mathcal{N}_p(\boldsymbol{\mu}, \boldsymbol{\Sigma})$, we have $\mathbf{x} = \mathbf{A}\mathbf{y} + \boldsymbol{\mu}$ such that $\boldsymbol{\Sigma} = \mathbf{A}\mathbf{A}^{\top}$.
- **③** Using $\phi_0(\mathbf{t})$ to present the characteristic function of $\mathbf{x} \sim \mathcal{N}_p(\boldsymbol{\mu}, \boldsymbol{\Sigma})$.

Theorem 2

The characteristic function of ${\bf x}$ distributed according to $\mathcal{N}_p(\mu,{f \Sigma})$ is

$$\phi(\mathbf{t}) = \exp\left(\mathrm{i}\,\mathbf{t}^{ op}\boldsymbol{\mu} - \frac{1}{2}\mathbf{t}^{ op}\mathbf{\Sigma}\mathbf{t}\right).$$

for every $\mathbf{t} \in \mathbb{R}^p$.

We can use this theorem to prove $\mathbf{z} = \mathbf{D}\mathbf{x} \sim \mathcal{N}(\mathbf{D}\boldsymbol{\mu}, \mathbf{D}\boldsymbol{\Sigma}\mathbf{D}^{\top})$ easily.

The following theorem can be viewed as another definition of multivariate normal distribution.

Theorem 3

If every linear combination of the components of a random vector \mathbf{y} is normally distributed, then \mathbf{y} is normally distributed.

In other words, if the p-dimensional random vector \mathbf{y} leads to the univariate random variable

$$\mathbf{u}^{\mathsf{T}}\mathbf{y}$$

is normally distributed for any fixed $\mathbf{u} \in \mathbb{R}^p$, then \mathbf{y} is normally distributed.

Problem in Exam

Let $\mathbf{x} \sim \mathcal{N}_{\rho}(\boldsymbol{\mu}_1, \boldsymbol{\Sigma}_1)$, $\mathbf{y} \sim \mathcal{N}_{\rho}(\boldsymbol{\mu}_2, \boldsymbol{\Sigma}_2)$ and $\mathbf{z} = \mathbf{x} + \mathbf{y}$. Suppose that \mathbf{x} and \mathbf{y} are independent. Prove $\mathbf{z} \sim \mathcal{N}_{\rho}(\boldsymbol{\mu}_1 + \boldsymbol{\mu}_2, \boldsymbol{\Sigma}_1 + \boldsymbol{\Sigma}_2)$.

Use characteristic function to avoid using density.

Characteristic Function and Density

The characteristic function determines the density function uniquely (if the density exists).

Theorem 4

If the *p*-dimensional random vector \mathbf{x} has the density $f(\mathbf{x})$ and the characteristic function $\phi(\mathbf{t})$, then

$$f(\mathbf{x}) = \frac{1}{(2\pi)^p} \int_{-\infty}^{\infty} \cdots \int_{-\infty}^{\infty} \exp(-\mathrm{i} \, \mathbf{t}^{\top} \mathbf{x}) \, \phi(\mathbf{t}) \, \mathrm{d}t_1 \dots \mathrm{d}t_p.$$

See the proof in Section 10.6 of "Cramer, H. (1946). Mathematical Methods of Statistics. Princeton University Press".

Characteristic Function and Probability

If x does not have a density, the characteristic function uniquely defines the probability of any continuity interval.

Theorem 5

Let $\{F_j(x)\}$ be a sequence of cdfs, and let $\{\phi_j(t)\}$ be the sequence of corresponding characteristic functions. A necessary and sufficient condition for $F_j(x)$ to converge to a cdf F(x) is that, for every t, $\phi_j(t)$ converges to a limit $\phi(t)$ that is continuous at t=0. When this condition is satisfied, the limit $\phi(t)$ is identical with the characteristic function of the limiting distribution F(x).

See the proof in Section 10.7 of "Cramer, H. (1946). Mathematical Methods of Statistics. Princeton University Press"

Characteristic Function and Moments

If the *n*-th moment of random variable x, denoted by $\mathbb{E}[x^n]$, exists and is finite, then its characteristic function is n times continuously differentiable and

$$\mathbb{E}[x^n] = \frac{1}{\mathrm{i}^n} \frac{\mathrm{d}^n \phi(t)}{\mathrm{d}t^n} \bigg|_{t=0},$$

which is because of

$$\frac{\mathrm{d}^{n}\phi(t)}{\mathrm{d}t^{n}} = \frac{\mathrm{d}^{n}}{\mathrm{d}t^{n}} \mathbb{E}\left[\exp(\mathrm{i}\,tx)\right]$$
$$= \mathbb{E}\left[\frac{\mathrm{d}^{n}}{\mathrm{d}t^{n}}\exp(\mathrm{i}\,tx)\right]$$
$$= \mathbb{E}\left[(\mathrm{i}\,x)^{n}\exp(\mathrm{i}\,tx)\right]$$
$$= \mathrm{i}^{n}\,\mathbb{E}\left[x^{n}\exp(\mathrm{i}\,tx)\right].$$

Characteristic Function and Moments

For normal distributed random vector $\mathbf{x} \sim \mathcal{N}_p(\boldsymbol{\mu}, \boldsymbol{\Sigma})$ and its characteristic function $\phi(\mathbf{t}) = \exp\left(\mathrm{i}\,\mathbf{t}^\top \boldsymbol{\mu} - \frac{1}{2}\mathbf{t}^\top \boldsymbol{\Sigma} \mathbf{t}\right)$, we have

$$\mathbb{E}[x_h] = \frac{1}{\mathrm{i}} \frac{\mathrm{d}\phi(\mathbf{t})}{\mathrm{d}t_h} \bigg|_{\mathbf{t}=\mathbf{0}} = \frac{1}{\mathrm{i}} \left(\mathrm{i} \, \mu_h - \sum_{j=1}^p \sigma_{hj} t_j \right) \phi(\mathbf{t}) \bigg|_{\mathbf{t}=\mathbf{0}} = \mu_h$$

and

$$\mathbb{E}[x_h x_j] = \frac{1}{i^2} \frac{\partial^2 \phi(t)}{\partial t_h \partial t_j} \bigg|_{\mathbf{t} = \mathbf{0}}$$

$$= \frac{1}{i^2} \left(\left(-\sum_{k=1}^p \sigma_{hk} t_k + i \mu_h \right) - \sigma_{hj} \right) \left(\left(-\sum_{k=1}^p \sigma_{kj} t_k + i \mu_j \right) - \sigma_{hj} \right) \phi(\mathbf{t}) \bigg|_{\mathbf{t} = \mathbf{0}}$$

$$= \sigma_{hj} + \mu_h \mu_j.$$

Thus, we have

$$\operatorname{Var}(x_h) = \mathbb{E}[x_h - \mu_h]^2 = \mathbb{E}[x_h^2] - \mu_h^2 = \sigma_{hh},$$
$$\operatorname{Cov}(x_h, x_i) = \mathbb{E}[(x_h - \mu_h)(x_i - \mu_i)] = \mathbb{E}[x_h x_i] - \mu_h \mu_i = \sigma_{hi}.$$

Characteristic Function and Moments

If all the moments of a distribution exist, then the cumulants are the coefficients κ in

$$\log \phi(\mathbf{t}) = \sum_{s_1=0}^{\infty} \cdots \sum_{s_p=0}^{\infty} \kappa_{s_1 \dots s_p} \frac{(\mathrm{i} t_1)^{s_1} \dots (\mathrm{i} t_p)^{s_p}}{s_1! \dots s_p!}.$$

In the case of the multivariate normal distribution, we have

$$\kappa_{100...0} = \mu_1, \quad \kappa_{010...0} = \mu_2, \quad \dots \quad \kappa_{000...1} = \mu_p,$$

and

$$\kappa_{200...0} = \sigma_{11}, \quad \kappa_{110...0} = \sigma_{12}, \quad \dots \quad \kappa_{000...2} = \sigma_{pp}.$$

The cumulants for which $\sum s_i > 2$ are 0.

Outline

1 Multivariate Normal Distribution (Conditional Distribution)

2 Characteristic Function

3 Maximum Likelihood Estimator of Mean and Covariance

Given a sample of (vector) observations from a p-variate (non-singular) normal distribution, we ask for estimators of the mean vector μ and the covariance matrix Σ of the distribution.

Suppose our sample of N observations on the $\mathbf{x}_1, \mathbf{x}_2, \dots, \mathbf{x}_N$, which are distributed according to $\mathcal{N}(\boldsymbol{\mu}, \boldsymbol{\Sigma})$, where N > p. The likelihood function is

$$\begin{split} L &= \prod_{\alpha=1}^{N} \textit{n}(\mathbf{x}_{\alpha} \mid \boldsymbol{\mu}, \boldsymbol{\Sigma}) \\ &= \frac{1}{(2\pi)^{\frac{pN}{2}} \left(\det(\boldsymbol{\Sigma}) \right)^{\frac{N}{2}}} \exp \left[-\frac{1}{2} \sum_{\alpha=1}^{N} (\mathbf{x}_{\alpha} - \boldsymbol{\mu})^{\top} \boldsymbol{\Sigma}^{-1} (\mathbf{x}_{\alpha} - \boldsymbol{\mu}) \right]. \end{split}$$

The likelihood function is

$$L = \frac{1}{(2\pi)^{\frac{pN}{2}} \left(\det(\mathbf{\Sigma}) \right)^{\frac{N}{2}}} \exp \left[-\frac{1}{2} \sum_{\alpha=1}^{N} (\mathbf{x}_{\alpha} - \boldsymbol{\mu})^{\top} \mathbf{\Sigma}^{-1} (\mathbf{x}_{\alpha} - \boldsymbol{\mu}) \right].$$

The vectors $\mathbf{x}_1, \mathbf{x}_2, \dots, \mathbf{x}_N$ are fixed at the sample values and L is a function of $\boldsymbol{\mu}$ and $\boldsymbol{\Sigma}$.

The logarithm of the likelihood function is

$$\ln L = -\frac{PN}{2} \ln 2\pi - \frac{N}{2} \ln \left(\det(\mathbf{\Sigma}) \right) - \frac{1}{2} \sum_{\alpha=1}^{N} (\mathbf{x}_{\alpha} - \boldsymbol{\mu})^{\top} \mathbf{\Sigma}^{-1} (\mathbf{x}_{\alpha} - \boldsymbol{\mu}).$$

Since $\ln L$ is an increasing function of L, the maximum likelihood estimators of μ and Σ are the vector and the positive definite matrix that maximize $\ln L$.

Let the mean vector be

$$\bar{\mathbf{x}} = \frac{1}{N} \sum_{\alpha=1}^{N} \mathbf{x}_{\alpha} = \begin{bmatrix} \frac{1}{N} \sum_{\alpha=1}^{N} x_{1\alpha} \\ \vdots \\ \frac{1}{N} \sum_{\alpha=1}^{N} x_{p\alpha} \end{bmatrix} = \begin{bmatrix} \bar{x}_{1} \\ \vdots \\ \bar{x}_{p} \end{bmatrix}$$

where

$$\mathbf{x}_{lpha} = egin{bmatrix} x_{1lpha} \ dots \ x_{eta} \end{bmatrix} \quad ext{and} \quad ar{x}_i = rac{1}{N} \sum_{lpha=1}^N x_{ilpha}.$$

Let the matrix of sums of squares and cross products of deviations about the mean be

$$\mathbf{A} = rac{1}{N} \sum_{lpha=1}^N (\mathbf{x}_lpha - ar{\mathbf{x}}) (\mathbf{x}_lpha - ar{\mathbf{x}})^ op$$

Theorem 6

If $\mathbf{x}_1, \mathbf{x}_2, \dots, \mathbf{x}_N$ constitute a sample from $\mathcal{N}(\mu, \mathbf{\Sigma})$ with p < N, the maximum likelihood estimators of μ and $\mathbf{\Sigma}$ are

$$\hat{\boldsymbol{\mu}} = \bar{\mathbf{x}} = \frac{1}{N} \sum_{\alpha=1}^{N} \mathbf{x}_{\alpha} \quad \text{and} \quad \hat{\boldsymbol{\Sigma}} = \frac{1}{N} \sum_{\alpha=1}^{N} (\mathbf{x}_{\alpha} - \bar{\mathbf{x}}) (\mathbf{x}_{\alpha} - \bar{\mathbf{x}})^{\top}$$

respectively.

Lemma 1

If $\mathbf{D} \in \mathbb{R}^{p \times p}$ is positive definite, the maximum of

$$f(\mathbf{G}) = -N \ln \det(\mathbf{G}) - \operatorname{tr}(\mathbf{G}^{-1}\mathbf{D})$$

with respect to positive definite matrices **G** exists, occurs at $\mathbf{G} = \frac{1}{N}\mathbf{D}$.

The maximum likelihood estimators of functions of the parameters are those functions of the maximum likelihood estimators of the parameters.

Theorem 7

Let $f(\theta)$ be a real-valued function defined on a set $\mathcal S$ and let ϕ be a single-valued function, with a single-valued inverse, on $\mathcal S$ to a set $\mathcal S^*$. Let

$$g(\theta^*) = f\left(\phi^{-1}(\theta^*)\right)$$
.

Then if $f(\theta)$ attains a maximum at $\theta = \theta_0$, then $g(\theta^*)$ attains a maximum at $\theta^* = \theta_0^* = \phi(\theta_0)$. If the maximum of $f(\theta)$ at θ_0 is unique, so is the maximum of $g(\theta^*)$ at θ_0^* .

Corollary 2

If on the basis of a given sample $\hat{\theta}_1,\ldots,\hat{\theta}_m$ are maximum likelihood estimators of the parameters θ_1,\ldots,θ_m of a distribution, then $\phi_1(\hat{\theta}_1,\ldots,\hat{\theta}_m),\ldots,\phi_m(\hat{\theta}_1,\ldots,\hat{\theta}_m)$ are maximum likelihood estimator of $\phi_1(\theta_1,\ldots,\theta_m),\ldots,\phi_m(\theta_1,\ldots,\theta_m)$ if the transformation from θ_1,\ldots,θ_m to ϕ_1,\ldots,ϕ_m is one-to-one. If the estimators of θ_1,\ldots,θ_m are unique, then the estimators of ϕ_1,\ldots,ϕ_m are unique.

Corollary 3

If $\mathbf{x}_1, \ldots, \mathbf{x}_N$ constitutes a sample from $\mathcal{N}(\boldsymbol{\mu}, \boldsymbol{\Sigma})$, let $\rho_{ij} = \sigma_{ij}/(\sigma_i \sigma_j)$. Then the maximum likelihood estimator of ρ_{ij} is

$$\hat{\rho}_{ij} = \frac{\sum_{\alpha=1}^{N} (x_{i\alpha} - \bar{x}_i)(x_{j\alpha} - \bar{x}_j)}{\sqrt{\sum_{\alpha=1}^{N} (x_{i\alpha} - \bar{x}_i)^2} \sqrt{\sum_{\alpha=1}^{N} (x_{j\alpha} - \bar{x}_j)^2}}$$

If $\phi: \mathcal{S} \to \mathcal{S}^*$ is not one-to-one, we let

$$\phi^{-1}(\boldsymbol{ heta}^*) = \{ oldsymbol{ heta} : oldsymbol{ heta}^* = \phi(oldsymbol{ heta}) \}.$$

and define (the induced likelihood function)

$$g(\theta^*) = \sup\{f(\theta) : \theta^* = \phi(\theta)\}.$$

If $heta=\hat{ heta}$ maximize f(heta), then $heta^*=\phi(\hat{ heta})$ also maximize $g(heta^*)$.
